

Test ADO.NET Gr. A

Time: 1h25m

Based on the attached ERD diagram and the `create.sql` script, create a WebApi application and complete the following tasks using ADO.NET.

Task1.

Prepare an endpoint `/api/vendors` that responds to **HTTP GET** requests. The endpoint should return data about all vendors present in the database along with the products they offer. Additionally, it should handle an optional query parameter **"name"** that allows filtering the result collection based on the vendor's name.

Example endpoints:

- `GET /api/vendors`
- `GET /api/vendors?name=Ama`
- `GET /api/vendors?name=Amazon`

Hint: Use the **LIKE** statement for filtering.

The required response format can be found in the `GET.json` file.

Task2.

Prepare an endpoint `/api/vendors` that responds to **HTTP POST** requests. The endpoint should allow adding a new vendor to the database, along with optionally assigning products they offer from the range of products available in the database.

The required format of the submitted data can be found in the `POST.json` file.

Scoring

Each endpoint is worth 12 points. An additional 6 points are allocated for naming conventions and application architecture. In total, you can earn 30 points.

Points may be deducted for:

- Using incorrect naming conventions, unclear variable names, or messy code: up to -4 points
- Incorrect HTTP response codes: up to -5 points
- Not separating database communication into a dedicated layer: up to -10 points

- Lack of dependency injection: up to -5 points
- Missing .gitignore file or unnecessary files in the repository (bin, obj): -50%
- Writing code that communicates with the database synchronously: up to -5 points

Notes

- A program that does not compile – zero points for the test
- A program not stored in a GitHub repository – zero points for the test
- A plagiarized program – final grade of 2

Using AI tools or solving tasks non-independently during the test will result in failing the course.
