

Test ADO.NET Gr. D

Time: 1h25m

Based on the attached ERD diagram and the `create.sql` script, create a WebApi application and complete the following tasks using ADO.NET.

Task1.

Prepare an endpoint `/api/makers/{id:int}` that responds to **HTTP GET** requests. The endpoint should return data about the specified manufacturer, the products they produce, and who sells them.

Example endpoints:

- GET `/api/makers/1`
- GET `/api/makers/2`

The required response format can be found in the `GET.json` file.

Task2.

Prepare an endpoint `/api/makers` that responds to **HTTP POST** requests. The endpoint should allow adding a new manufacturer to the database, along with optionally creating the products they offer.

The required format of the submitted data can be found in the `POST.json` file.

Scoring

Each endpoint is worth 12 points. An additional 6 points are allocated for naming conventions and application architecture. In total, you can earn 30 points.

Points may be deducted for:

- Using incorrect naming conventions, unclear variable names, or messy code: up to -4 points
- Incorrect HTTP response codes: up to -5 points
- Not separating database communication into a dedicated layer: up to -10 points
- Lack of dependency injection: up to -5 points
- Missing `.gitignore` file or unnecessary files in the repository (bin, obj): -50%

- Writing code that communicates with the database synchronously: up to -5 points

Notes

- A program that does not compile – zero points for the test
- A program not stored in a GitHub repository – zero points for the test
- A plagiarized program – final grade of 2

Using AI tools or solving tasks non-independently during the test will result in failing the course.
